Is Bottled Water Shortchanging Your Oral Health?

On any given day, many of us turn to bottled water to help quench our thirst. On average, Americans drink approximately 2.3 servings of bottled water per day. Although bottled water is portable and convenient, drinking it may shortchange you of an important tap water benefit: fluoride.

For the past 50 years, many U.S. communities have added fluoride to drinking water. As a result, the number of dental caries (tooth decay) declined sharply in those communities. Fluoride — whether it is applied topically through toothpastes or fluoride rinses, or ingested through drinking water — helps prevent cavities by neutralizing the effects of the acids that cause decay.

However, more and more of us are drinking bottled rather than tap water. According to the International Bottled Water Association (IBWA), almost half of all Americans drink bottled water daily.

According to the IBWA, only about 20 U.S. bottlers sell fluoride-added water. Although the fluoride content of bottled water varies, many might not contain an adequate amount of fluoride to prevent tooth decay. This is especially important if your primary drinking water source is bottled water. Children and adults should be certain to get adequate amounts of fluoride, as it helps ward off tooth decay throughout your lifetime. In addition, fluoride helps prevent root decay, which is especially problematic for adults who experience receding gums.

Protect You and Your Family's Oral Health

If you are concerned about fluoride intake — either yours or that of your family — talk to your dentist. In addition to getting the right amount of fluoride, remember these key components to protecting your family's oral health:

- Brush and floss every day
- Eat a balanced, nutritional diet
- Make regular dental visits
